Abstract

This paper addresses the selection of partners in innovation networks. It builds on the existing literature to develop an integrative framework that encompasses the main factors identified as influencing selection of partners by young knowledge-intensive firms. It considers that both persistence and novelty are present in the network building process, and so integrates several explanations advanced by the literature: social capital, imprinting and inertia for tie persistence; network embeddedness and proximity for new tie selection.

Using a rare event logit model, we estimate the likelihood of selecting an innovation partner using data about the partnerships established by young Portuguese biotechnology firms, purposefully collected through questionnaire-based face-to-face interviews, complemented with documentary information. The results uncover different network building strategies in terms of partner selection to access the different types of resource needed for innovation and highlight the advantages of adopting an integrated framework.

Sumário

Este trabalho analisa a seleção de parceiros em redes de inovação. Com base na análise da literatura existente desenvolve-se um quadro que integra os principais fatores que influenciam a forma como novas empresas intensivas em conhecimento selecionam os seus parceiros de inovação. Considera-se a relevância quer da persistência quer da novidade e procura-se uma integração de várias explicações presentes na literatura: capital social, *imprinting* e inércia no caso da persistência; inserção em redes e proximidade no caso da seleção de novos parceiros.

Com base num modelo logit para eventos raros, estima-se a probabilidade de um parceiro ser selecionado, usando dados sobre as parcerias estabelecidas pelas empresas portuguesas de biotecnologia. Os dados foram recolhidos através de entrevistas semi-estruturadas presenciais, complementadas por informação documental. Os resultados revelam diferentes estratégias de construção de redes e sublinham as vantagens da utilização de um quadro integrando variáveis que habitualmente são usadas separadamente.

1. Introduction

Understanding how firms select their innovation partners is vital to grasp the evolution of inter-organisational networks. The process of partner selection has been addressed in the literature, but research tends to focus on individual factors and/or to have an exclusively theoretical approach. This paper builds on the existing literature to develop an integrative framework that encompasses the main factors identified as influencing selection of innovation partners by young knowledge-intensive firms; and assesses their combined impact on the probability of partner selection.

The selection of partners is designed (Nooteboom, 2008) and affected by search costs and uncertainty, raising adverse selection and moral hazard problems (Kirkels and Duysters, 2010). When selecting a partner, firms can rely on their past relationships or look for a new organisation. In the first case, firms select organisations they know from prior partnerships (Gulati, 1995a) or with whom entrepreneurs have personal relations (Hallen, 2008) and we are in the presence of persistence and of path dependent processes (Walker et al, 1997). In the second case, new actors join the network, bringing novelty and variety that are vital for innovation (McEvily and Zaheer, 1999) and their selection is driven by evaluation mechanisms, since there is no direct knowledge of partners' capabilities (Li and Rowley, 2002).

Despite the relevant contributions of previous studies, the process of partner selection is not yet fully understood, especially in the case of new firms (Grossman et al, 2012). In this paper we argue that it is necessary to adopt an integrated perspective, considering simultaneously the several (complementary) factors identified so far; and to submit theoretical propositions to empirical testing. Thus the paper proposes a framework that: i) combines various factors identified in previous research as influencing partner selection, relating them with persistence and novelty; ii) addresses network building as a sequential process, along which decisions concerning partner selection are made, being influenced by these factors.

On the basis of this framework, we build and empirically test a (logit) model of partner selection that takes in consideration both persistence effects (associated with selection of partners known from previous relationships) and evaluation mechanisms (associated with the selection of novel, unknown partners).

2 Theoretical background

2.1 Tie persistence

Tie persistence is an important mechanism in the construction of inter-organisational networks. Previous research on alliances uncovered firms propensity to establish relations with organisations they know from prior partnerships (Gulati, 1995a), resulting in path-dependent routines on partner selection (Li and Rowley, 2002). Trust and learning effects are also described as arising from the repeated interaction in previous relationships (Gulati, 1995a; Hallen, 2008). Thus, tie persistence contributes for the reduction of search costs and uncertainty, since it allows firms to discern capable and reliable partners, based on previous experiences (Gulati and Gargiulo, 1999).

Start-up firms do not have these previous alliance-based relationships. So, entrepreneurship scholars highlight the importance of entrepreneurs' previous personal relations (Adobor, 2006), often related with their social capital (Anderson et al, 2007), in firm creation process. Since the professional and academic trajectory of the entrepreneurs is a basic element in the formation of their personal networks, it is often assumed that relationships established along this trajectory become automatically part of the early network of the new firm (Shane and Stuart, 2002). In the limit, the firm's network at start-up is equated with its entrepreneurs' social capital (Hsu, 2007). However, elsewhere we found that trajectory ties are not automatically transformed in firms' ties (Fontes et al, 2012). Rather, entrepreneurs assess the utility of their personal contacts and only select those considered as valuable for the firm.

Ties that originate from the entrepreneurs' social capital have several advantages. They are usually characterised by higher levels of trust, which facilitate communication and

information exchanges (Burt, 1997). Moreover, since they are often based on shared experiences, there is a good understanding of the potential contributions they can offer (Koka and Prescott, 2002). These experiences may also have led to the development of cognitive proximity, facilitating the transmission of knowledge, particularly when it is complex or less structured (Breschi and Lissoni, 2001).

However, exactly because these ties are associated with the entrepreneurs' personal trajectory, they may be less useful when it comes to accessing resources and competences that are more distant from the entrepreneur's own experience (Ensley and Hmieleski, 2005). Scholars point to the advantages of diversity in network composition, since ties with similar actors have reduced benefits in terms of information and knowledge (Nooteboom, 1999). Therefore, establishing relations with a diverse set of actors lessens the risks of redundancy (Burt, 1992) and over-embeddedness (Adobor, 2006, Uzzi, 1997) and facilitates the access to different types of knowledge (Baum et al., 2000).

Scholars also stress the importance of decisions made at start-up in the subsequent development of the company. These are described as having an "imprinting effect" (Stinchcombe, 1965; Eisenhardt and Schoonhoven, 1990), since they shape firms' choices regarding resource mobilisation, competence development and search for partners. Regarding the latter, Milanov and Fernhaber (2009) found that initial partnerships have a long term impact on firms' access to network resources, since the network size and centrality of the initial partners influence the subsequent size of the new venture's network.

As firms evolve, behavioural persistence at organisational level, related with the prevalence of routines and inertia, emerges (Kim et al, 2006). The development of relation-specific routines reduces the probability of alliance partner replacement based solely on economic evaluation and brings an element of rigidity into the construction of networks (Kim et al, 2006). Even when a new partner can provide better resources than the existing one, firms may maintain the old relation (Reuer et al, 2002), since it has allowed relation-specific assets to be built (Ebers, 1999). In this sense, network inertia is not a signal of poor management, but a by-product of successfully managed networks (Kim et al, 2006).

2.2 New ties

The satisfaction of resource needs also relies on the establishment of new relationships, intentionally built, which bring novel information and knowledge (Baum et al, 2000). The selection of the new network members is driven by evaluation mechanisms, since there is no direct knowledge of partners' capabilities (Li and Rowley, 2002).

Scholars sustain that the selection of unknown organisations has to be understood in the context of existing networks. The embeddedness in inter-organisational networks enables the access to some information about the quality of potential partners and therefore reduces the uncertainty about them (Human and Provan, 2000; Glückler and Armbrüster, 2003). In this sense, an organisation's new tie opportunities are shaped by the characteristics of the network where it is embedded (Grossman et al, 2012).

The structure of the whole network influences each actor's actions, since its position in the network constrains the set of available actions (Marsden, 1981; Gulati, 1998). Some studies show that firms tend to form partnerships with organisations they know indirectly, i.e., with whom they share a partner (Gulati, 1995b; Hallen, 2008), or with organisations that occupy a central position in the network, thus signalling their quality and reliability as sources of resources (Powell et al, 1996; Gulati and Garguilo, 1999, Ahuja, 2000). Therefore, although the configuration of the whole network is influenced by the

characteristics of the dyads, the whole is more than the sum of its parts and, in turn, affects the occurrence of a tie.

Another line of research departs from the embeddedness perspective and provides some insights about the selection of “socially distant” ties. Some studies stress the role of “assortative mechanisms”, i.e., of the compatibility and complementarity between partners’ attributes (Rivera et al, 2010). Thus, new ties are preferably formed with organisations with which firms share some traits, since similarity (homophily) favours trust-building and ease of communication (McPherson et al, 2001). Following this line of reasoning, some authors focus on various forms proximity (Boschma and Frenken, 2010; Nooteboom et al, 2007) as a factor that facilitates resource exchanges.

The importance of localised resource exchange has been extensively discussed in the literature, especially in the case of knowledge (Breschi and Lissoni, 2001), but also for non-technological resources (Sorenson and Stuart, 2001). Scholars stress the importance of co-localisation for learning and exchange of information and knowledge processes (Lorenzen, 2007).

More recently, scholars have pointed to the importance of non-geographical forms of proximity. Some degree of cognitive proximity is necessary to assess the value of the knowledge produced, fully understand it and absorb and apply it effectively (Cohen and Levinthal, 1990). Institutional/organisational proximity helps to manage resource exchange and reduces transactions costs (Boschma, 2005). However, for knowledge exchange, Boschma and Frenken (2010) identified a proximity paradox: too much proximity between organisations can reduce firms’ innovative performance. Similarly, Nooteboom (2000) found an inverted U-shape relation between cognitive distance and innovative performance, and thus evidence of the existence of an optimal distance.

2.3 Building an integrated framework

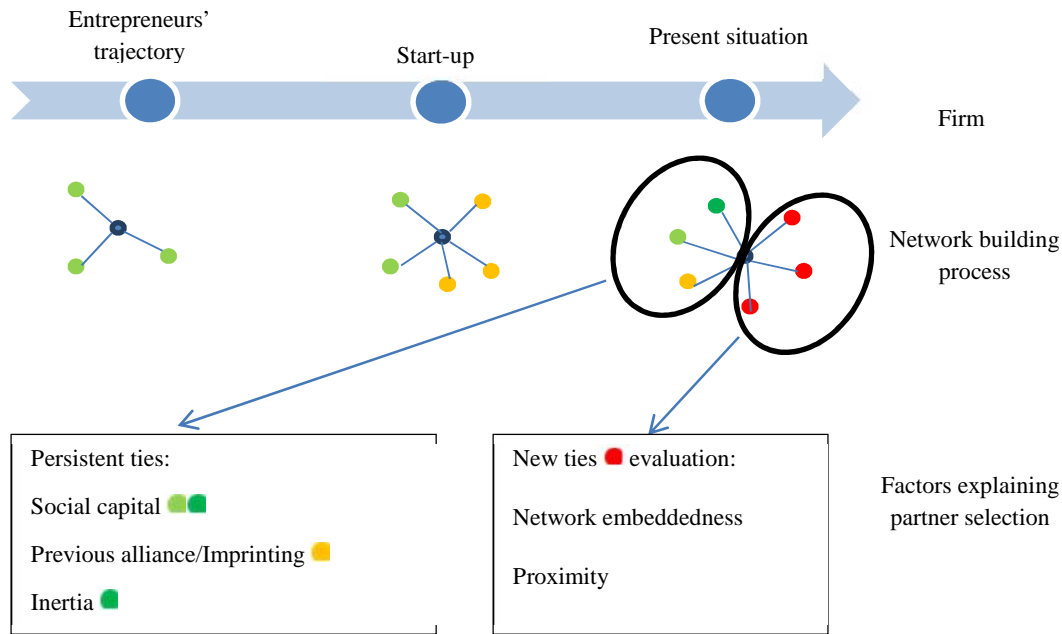

In order to pursue innovation activities, firms rely on a set of internal resources and competences which they combine with external ones, accessed via market and non-market transactions. Networks are considered essential in this process of resource gathering (Ozman, 2009), particularly in science-based sectors (Baum et al, 2000). So, in this research we consider that network partners provide resources for the innovation process.

Previous research has shown that the type of resource being accessed influences the type of networks being established (Sammorra and Biggiero, 2008; Sousa et al, 2011). Thus, it is also likely to influence the process of partner selection. Therefore, we distinguish three types of resources - S&T knowledge, complementary assets and legitimacy/ credibility – and look at the process of partner selection in each case.

The literature has also shown that resources requirements change over time (Delmar and Shane, 2004). So, partners that are useful at a certain point of the firm's history may be useless at other points. Additionally, firms can make mistakes in selecting partners and subsequently correct them, or they may change their strategy with impact on the resource needs and thus on the type of partners required (Druilhe and Garnsey, 2004, Costa et al, 2004). These facts have implications for the dynamics of network building. Therefore, inter-organisational networks change on a continuous basis (Kim et al, 2006). To acknowledge this, we adopt a sequential approach to the process of network building in which three different phases are considered: entrepreneurs’ academic and professional trajectory up to start-up, start-up (the year of formal creation and the two subsequent years of activity) and present moment (the time the information was collected).

The proposed framework (Figure 1) introduces the possibility of maintaining previous partners (or not), or selecting new ones (or not) on a continuous basis. Therefore, we consider that, at start-up, firms can mobilise entrepreneurs' pre-existing ties with organisations from their trajectory, or build new relations. Similarly, in the present moment firms can maintain the relationships with start-up partners or renew previous relationships with trajectory organisations not yet mobilized; or they can build new ones. As mentioned above, the selection of these new ties is driven by evaluation mechanisms, since there is no direct knowledge of partners' capabilities (Li and Rowley, 2002).

Figure 1 – Integrated framework

Hereby the framework enables us to consider both persistent and new ties; and to integrate the several arguments advanced in the literature to explain partner selection, namely social capital, imprinting and inertia for tie persistence, and network embeddedness and proximity for new tie selection.

3 Method

3.1 Empirical strategy and data sources

We model the probability that a firm i selects an organisation j as a partner and thus forms a tie to access resources for innovation. Following other studies of tie formation, we use a logit model, considering all feasible dyads (Gulati, 1995b; Stuart, 1998; Gulati and Gargiulo, 1999; Roijakkers et al, 2005).

The analysis is based on the ties established by 13 young Portuguese biotechnology firms¹. Our data base includes, for each firm, all feasible dyads, both those that have materialised and those that have not. We consider that all the 459 organisations present in the current sectoral innovation network (Figure A1 in appendix) could have been selected by each of

¹ This sample was obtained from a larger research project, that encompassed the universe of Portuguese molecular biology firms (23 firms) (Salavisa and Fontes, 2012), from which were selected the firms over 3 years old.

the 13 firms. In addition we also include, for each firm, the organisations from the entrepreneurs' trajectory and the partners that were chosen at start-up, but are not present in the current sectoral innovation network, i.e. those that have decayed.

Considering all feasible dyads as a sampling procedure poses two empirical difficulties (Sorenson and Stuart, 2001). First, the observations may be interdependent because each firm appears in many dyads creating a common-actor effect. Second, the materialisation of a dyad in this sample is a rare event. Given the fact that the largest innovation network for a firm is composed of 182 organisations and that the feasible dyads for each firm exceed 500, this would imply a large number of zeros. In fact, the database includes 968 materialized dyads in a set of 6786 feasible ones. So, the ratio of materialised to non-materialised dyads is very small (14%).

For these reasons, drawing on the work of Sorenson and Stuart (2001) we have adopted a rare event logit model using the *relogit* stata procedure (Tomz et al, 1999) and applied a choice-based sampling procedure.

Therefore the sample used in the regressions includes all the materialized dyads (irrespective of the moment when they took place, i.e. on the entrepreneurs' trajectories, at start-up or at the present moment) and a matched sample of relations that have not occurred. These were randomly chosen from the list of organisations present in the current sectoral network. Thus, the matched sample includes 1936 dyads (both materialised and non-materialized) involving 660 partner organisations. As a result each partner enters in the sample an average of 2.9 times.

Data collection was conducted through face-to-face interviews, based on a semi-structured questionnaire. Data was collected on the entrepreneurs' personal network and on its role to firm start-up and early growth, permitting to obtain fine grained information about the people who were/are important during the two periods, including the origin of the relationships and the type, nature and relevance of their respective contributions. Data was equally collected on firm innovation and technological strategies and activities, including cooperation arrangements (both formal and informal). This was complemented by documentary information that included: the Curriculum Vitae (CV) of the entrepreneurs, published data about formal collaborative projects, partnerships and patents, and a variety of information about the entrepreneurs' personal trajectories and firm formation histories.

The data obtained enabled the (re)construction of entrepreneurs' academic and professional trajectories and of firms' innovation networks, both at start-up and at the moment of the interview (for a detailed description see Sousa, 2012). It has also permitted to distinguish between ties established to access the three types of resource defined: S&T knowledge, complementary assets and legitimacy/credibility. The concept of multiplex tie is used to acknowledge the possibility that the same partner acts as a source of two (duplex) or three (triplex) different types of resources. Table 1 presents some descriptive statistics about the number of dyads for each moment and resource.

Table 1 – Number of dyads in firms' innovation networks

Moment	Resource	Mean	Std. Dev.	Min	Max
Start-up	S&T knowledge	7	7.2	1	25
	Complementary assets	7	2.9	2	14
	Legitimacy/credibility	5	4.2	1	16
	All (innovation network)	14	10.0	3	36
Present	S&T knowledge	18	23.9	1	91
	Complementary assets	45	42.5	4	119
	Legitimacy/credibility	4	4.1	0	15
	All (innovation network)	61	55.8	6	182

3.2 Variables

The dependent variable in all models, tie formation, is a dichotomous variable for the occurrence of a tie, which mirrors the selection of a partner. It assumes the value of one when a certain organisation j is mobilized for innovation purposes by a firm i . We start by considering all resources and then distinguish between S&T knowledge, complementary assets and legitimacy/credibility. So, four different models are estimated.

The independent variables are organised in different groups, capturing all the dimensions referred in the extant literature already mentioned. Descriptive statistics are presented in Table A1 (Appendix).

3.2.1 Variables capturing tie persistence

To capture the effect of the entrepreneur's *social capital* we consider a variable that indicates if the dyad derives from the entrepreneur's previous academic and professional trajectory (TRAJ $_{ij}$). To capture the effect of *previous alliance/imprinting* we consider a variable that indicates the existence of the dyad at start-up. Dyads are distinguished according to the resource was being accessed: INNOVSU $_{ij}$ (all resources), KNOWSU $_{ij}$ (knowledge), CASU $_{ij}$ (complementary assets) and LC $_{ij}$ (legitimacy/credibility). To capture the effect of *network inertia* we consider a variable that indicates whether a relation origination from the entrepreneur's trajectory was activated to access resources for innovation at start-up (INER $_{ij}$).

3.2.2 Variables capturing tie evaluation

To capture the effect of *network embeddedness* the model includes two variables. To indicate the partner's positioning in the sectoral network, we use a measure of network centrality: outdegree centrality of each partner in the previously existing network (POC). This measure shows the number of ties that depart from a partner: central partners provide resources to a large number of firms and are characterised by intensive activity.

To capture the *share of third partners*, and since we do not have indirect ties in the (re)constructed sectoral network, we resort to the network concept of clique. A clique is a sub-set of actors in which each one is connected to all others. Since we want to capture the existence of indirect ties, the 2-clique concept is used, i.e., a clique where the actors are connected directly or through a common neighbour and only cliques with more than three members are considered. So, our variable (NCLIQUES) considers the number of 2-cliques in which both the firm i and the partner j are present, excluding the existence of a direct tie.

To capture *geographical proximity* (PGEO) between the firm and its partners, each organisation's location was considered and partners were classified in two groups: national (Portuguese) and foreign. To capture *organisational proximity*, we follow Broekel and Boschma (2012), who draw on Metcalfe's concept of organisational proximity based on the similarity of routines and incentive mechanisms, to argue that a profit and a non-profit organisation have a low degree of organisational proximity, which lowers their probability to connect and collaborate. Therefore, we distinguish different types of organisations - biotechnology firms, firms from other sectors, universities and research centres, hospitals, S&T parks, financial institutions and other organisations, (eg. trade and professional associations and government agencies) - and include one variable to capture the culture of a profit organisation (PFIRM) and one to capture the culture of an academic organisation (PUNIV). However this distinction should be regarded with care in the case of science-based firms, which often perform an intermediate function between science and the market

(Fontes, 2005; Stuart et al, 2007) and whose funders are frequently scientists. In fact, these firms tend to be close to academic culture (Ensley and Hmieleski, 2005).

3.2.3 Control variables

Our model controls for the characteristics of the previous dyads, since they may affect the development of relation-specific assets (Kim et al, 2006). Therefore we consider the intensity of the dyad at start-up in terms of its multiplexity (TMULTSU). At start-up, entrepreneurs will tend to choose organisations perceived to offer access to several resources, in the absence of a precise understanding of which resources are best suited for the new company and its growth (Grossman et al, 2012). Thus fewer partners can give access to a variety of resources. This can influence the longevity of the relationship.

Firms' age (AGE) and size (SIZE) are equally included, since they may influence structural inertia (Kim et al, 2006) and also the tendency to activate entrepreneurs' social capital (Hite and Hesterly, 2001).

Finally, the centrality of the firm in the whole network can influence the ability to identify and gain access to partners (Bae and Gargiulo, 2004), as well as lead to the development and accumulation of network capabilities (Foss, 1999) affecting the choice of partners and the survival of the relationship. Therefore, the indegree centrality of the firm in the previously existing network (FIC) is considered in the model. The indegree centrality measures the total number of ties directed towards the firm. Thus a central firm receives resources from several different organisations, being characterised as very attractive

4. Results

Table 2 reports the results of the rare events logit models for partner selection in the various networks. Model 1 provides estimates of the probability of partner selection, in order to obtain the resources required for innovation. Models 2 to 4 provide estimates of the probability of partner selection in order to access scientific and technological knowledge, complementary assets and credibility/reputation,² respectively.

Results for model 1 show that both persistence and evaluation mechanisms affect the likelihood of tie formation. Regarding persistence, the existence of a prior relation at start-up (INNOVSU) and inertia (INER) increase the probability of selecting a specific partner, while social capital (TRAJ) reduces it. Regarding evaluation mechanisms, network embeddedness, both in terms of partner centrality (POC) and of share of third partners (NCLIQUES), increases the probability of selecting a specific partner, while geographical proximity and the fact that the partner has an academic organisational culture reduce it. Regarding control variables, intensity of the tie at start-up and firm centrality affect positively the probability of tie formation, while firm size reduces it.

² All models provide a good fit to the data. The chi-squared goodness-of-fit test for the change in the -2Loglikelihood value is statistically significant (Model 1: $2(12) = 238.25$, $p < .001$; Model 2: $2(12) = 183.02$, $p < .001$; Model 3: $2(12) = 351.45$, $p < .001$; Model 4: $2(12) = 394.73$, $p < .001$) providing support for acceptance of the models as significant logistic regressions. Furthermore, the overall rate of correct classification is very satisfactory: above 80% for all models. Observed sensitivity (i.e. the probability of predicting selection when it occurs) and specificity (i.e. the probability of predicting no selection when it does not occur) are high. Also the sensitivity/specificity analysis performed through the ROC curve reveals the high predictive power of these models. The presence of multicollinearity was verified in two ways: i) by inspection of the correlation matrix; and ii) running the corresponding multiple regression models and requesting the collinearity diagnostics. There is no evidence of strong linear relationships between independent variables, and the variance inflation factor (VIF) never exceeds 4, far below the often recommended threshold of 10.

Correct classification (%)	82.46	88.26	93.69	98.81

Note: numbers in brackets are the robust standard errors; *** p < 0.01; ** p < 0.05; * p < 0.1

Results for model 2 also reveal the relevance of persistence and evaluation mechanisms in the selection of knowledge partners. Comparing with Model 1, and in addition to differences in the magnitude of the coefficients, it is noteworthy the change of sign of the NCLIQUES and the of the PACADEMIC variables. For knowledge access purposes, these firms tend to select partners which have an academic culture and with which they share few other partners in the sectoral network.

Results for model 3 indicate the existence of a smaller number of significant explanatory variables for the selection of partners to access complementary assets, although both factors – persistence and evaluation - appear as relevant. Inertia and partner centrality have no effect in partner selection. Comparing with Model 1, we find that geographical proximity (PGEO) now increases the probability of partner selection, indicating the relevance of this factor in the access to complementary assets.

Results for Model 4 show that in the access to legitimacy/credibility neither network embeddedness nor proximity affect partner selection, which is solely driven by persistence. However, the results for the control variables suggest that persistence seems to be less relevant as firm ages, in line with previous research (Lechner et al, 2006).

5. Discussion and conclusion

This research provides evidence that contributes to on-going debates about the evolution of innovation networks, allowing a more in-depth understanding of the process of partner selection by young knowledge-intensive firms.

Previous research has shown that network building through partner selection involves both the persistence of previous partners and the inclusion of new ones. So, to understand processes of partner selection we have to consider the complementarity between persistence effects and evaluation mechanisms (Li and Rowley, 2002). Therefore, an integrated framework that considers elements of persistence and novelty was developed and tested.

Regarding persistence, three different explanatory factors, suggested by the extant literature, were considered: entrepreneurs' social capital, previous alliance/imprinting and network inertia. Results indicate that firms tend to select organisations they know from previous relations, to access all types of resources necessary for innovation. This result is in line with previous research on alliances (Gulati and Gargiulo, 1999), and with the imprinting literature (Milanov and Fernhaber, 2009). Previous ties seem to help firms in the choice of partners to include in their innovation networks.

Contrary to the arguments of the social capital literature, entrepreneurs' social capital decreases the likelihood of tie formation. This result may be related with the fact that we are considering partner selection at the firms' early growth phase and not at start-up. In fact, previous research has shown that the relevance of entrepreneurs' social capital decays during the process of firm development (Hite and Hesterly, 2001).

However, the positive and significant coefficients for the inertia variable, in line with the findings of previous research (Li and Rowley, 2002), indicate that the combination of social capital with previous alliance has a positive effect on the likelihood of tie formation. This repeated contact allows the development of relation-specific assets and routines that facilitate network building and management processes. Hence, only social capital that was already activated at start-up seems to have a positive role on the probability of a given organisation to be selected, namely to provide knowledge and legitimacy/credibility.

Entrepreneurs' social capital seems to have no effect on the likelihood of tie formation in access to complementary assets. This is possibly linked with the more arm's length nature of the relations established to access this type of resource and also to the biotechnology entrepreneurs' predominantly scientific/academic trajectory, which is less useful in accessing non-technological resources (Ensley and Hmieleski, 2005). Conversely, their social capital is particularly useful to access scientific and technological knowledge, as well to provide legitimacy, since the association with reputed research organisations or scientists can have a quality signalling and credibilisation effect (Luo et al, 2009).

But, as the construction of networks is not solely based on already known organisations, our framework also considers evaluation mechanisms linked with the choice of new members, namely network embeddedness and proximity between the firm and the partner.

The results show that the existing sectoral network influences the selection of innovation partners. Considering the aggregated innovation network, more central organisations, or organisations with which firms share a partner in the existing sectoral network, have a higher probability of being selected by firms. Therefore, the selection of partners is influenced by information about partners' quality collected through the network, either due to their positioning or to indirect ties.

However the breakdown by resource reveals significant differences in the signal and significance of network embeddedness variables. Centrality has no significant effect in the choice of partners granting access to complementary assets or to legitimacy/credibility. The share of third partners exerts opposite effects on the selection of partners in the case of knowledge (negative) and complementary assets networks (positive). So, results suggest the existence of different mechanisms of selection of partners to access different resources, in terms of network embeddedness, which are not captured in an aggregate analysis.

In the choice of knowledge sources firms prefer central partners with which they share few other partners. This suggests a need to connect to the "best" knowledge sources and to avoid the risks of over-embeddedness (Owen-Smith and Powell, 2004), but also to protect the knowledge from potential leakages (Hurmelinna-Laukkanen and Puumalainen, 2007). Previous research has concluded that these firms access knowledge through communities (cliques) with strong inner connections and, usually, a single connection to the rest of the network performed by an academic partner (Salavisa et al, 2012).

On the contrary, in choosing partners for accessing complementary assets, companies prefer organisation with which they share a large number of partners. The signal given by the network positioning of the partner is not relevant. Therefore, firms prefer to gather information about these partners through organisations with which they have a direct tie. Thus, clique membership is central in selecting partners to access complementary assets.

The effect of proximity in partner selection also differs between resources. To access knowledge firms prefer foreign academic partners; to access complementary assets they prefer national non-academic (although not necessarily for-profit) organisations. This result confirms that biotechnology firms' access to international academic knowledge is vital to their innovation processes, especially in more peripheral economies (Gilding, 2008, Fontes et al, 2012). It also confirms that the local context is important to provide the complementary assets for the opportunity exploitation (Cooke, 2002).

The selection of partners to achieve legitimacy/credibility is not affected by the network embeddedness variables neither by the proximity variables. This is consistent with the endorsement function played by these partners, which requires previous close interactions and the development of some trust (Shane and Stuart, 2002).

Summing up, the results highlight the relevance of considering an integrated framework that encompasses several explanations for persistence and novelty, which so far were addressed separately. They also uncover different network building strategies in terms of partner selection to access the different types of resources needed for innovation.

The results of this research are globally relevant and increase our understanding of the process of innovation partner selection. Further research will enable us to mitigate some limitations in the specification of the logit model, namely: to account for common-actor effect; to consider the interaction between the variables, since the several mechanisms are closely interwoven; to introduce other forms of proximity described in the literature, namely cognitive proximity; to refine the geographical proximity, considering the actual distance (in Km or travel hours) between the company and each of the partners.
